

Hints for OnlineJudge 10282:

This is a job for a HashMap (or unordered_map if you're using C++).

Reading the input is a bit tricky, since just calling `in.next()` (where "in" is the Scanner object) would not detect the blank line separating the dictionary entries from the subsequent text. Instead, read each dictionary entry by calling `in.nextLine()`, which returns a string containing both words (English and foreign) separated by a space. Then you can call the `.split(" ")` method on that String object to split it into an array of two strings. Once `in.nextLine()` gives an empty string, it's time to switch to reading in the words of the text to be translated.
